We report the first observation of the double strange baryon $\Xi(1620)^0$ in its decay to $\Xi^-\pi^+$ via $\Xi_c^+ \rightarrow \Xi^-\pi^+\pi^+$ decays based on a 980 fb^{-1} data sample collected with the Belle detector at the KEKB asymmetric-energy e^+e^- collider. The mass and width are measured to be $1610.4 \pm 6.0(\text{stat})_{-4.2}^{+6.1}(\text{syst}) \text{ MeV}/c^2$ and $59.9 \pm 4.8(\text{stat})_{-7.1}^{+2.8}(\text{syst}) \text{ MeV}$, respectively. We obtain 4.0σ evidence of the $\Xi(1690)^0$ with the same data sample. These results shed light on the structure of hyperon resonances with strangeness $S = -2$.

DOI: [10.1103/PhysRevLett.122.072501](https://doi.org/10.1103/PhysRevLett.122.072501)

The constituent quark model has been very successful in describing the ground states of the flavor SU(3) octet and decuplet baryons [1–3]. However, some of the observed excited states do not agree well with the theoretical prediction. It is thus important to study such unusual states, both to probe the limitation of the quark models and to spot unrevealed aspects of the quantum-chromodynamics (QCD) description of the structure of hadron resonances. Intriguingly, the Ξ resonances with strangeness $S = -2$ may provide important information on the latter aspect.

The quantum numbers of several nucleons and $S = -1$ hyperon resonances have been measured. Recently, there has been significant progress in the experimental study of charmed baryons by the Belle, BABAR, and LHCb Collaborations. In contrast, only a small number of Ξ states have been measured [1]. Neither the first radial excitation with the spin parity of $J^P = \frac{1}{2}^+$ nor a first orbital excitation with $J^P = \frac{1}{2}^-$ has been identified. Determination of the mass of the first excited state provides a vital test of our understanding of the structure of Ξ resonances. One candidate for the first excited state is the $\Xi(1690)$, which has a three-star rating on a four-star scale [1]. Another candidate is the $\Xi(1620)$, with a one-star rating [1]. If the $\frac{1}{2}^-$ state is found, it will be the doubly strange analogue to the $\Lambda(1405)$ state, which has been postulated as a candidate meson-baryon molecular state or a pentaquark [4].

Experimental evidence for the $\Xi(1620) \rightarrow \Xi\pi$ decay was reported in K^-p interactions in the 1970s [5–7]. The mass and width measurements are consistent but have large statistical uncertainties. The most recent study, in 1981, has not found this resonance [8]. There is a lingering theoretical

controversy about the interpretation of the $\Xi(1620)$ and $\Xi(1690)$ states [9–16], extending from their assignment in the quark model to their existence. This would be addressed with new high-quality experimental results for the first excited state with $S = -2$. The hadronic decays of charmed baryons governed by the $c \rightarrow s$ quark transition are a good laboratory to probe these strange baryons.

In this Letter, we study the decay $\Xi_c^+ \rightarrow \Xi^{*0}\pi^+$, $\Xi^{*0} \rightarrow \Xi^-\pi^+$ based on a data sample collected with the Belle detector at the KEKB asymmetric-energy e^+e^- (3.5 on 8 GeV) collider [17]. The charge conjugate mode is included throughout this Letter. The sample corresponds to an integrated luminosity of 980 fb^{-1} . The major part of the data was taken at the $\Upsilon(4S)$ resonance; in addition, smaller integrated luminosity samples were collected off resonance and at the $\Upsilon(1S)$, $\Upsilon(2S)$, $\Upsilon(3S)$, and $\Upsilon(5S)$. We use a Monte Carlo (MC) simulation sample to characterize the mass resolution, detector acceptance, and invariant mass distribution in the available phase space. The MC samples are generated with EVTGEN [18], and the detector response is simulated with GEANT3 [19].

The Belle detector is a large-solid-angle magnetic spectrometer that consists of a silicon vertex detector (SVD), a 50-layer central drift chamber (CDC), an array of aerogel threshold Cherenkov counters (ACC), a barrel-like arrangement of time-of-flight scintillation counters (TOF), and an electromagnetic calorimeter comprised of CsI(Tl) crystals (ECL); all these components are located inside a superconducting solenoid coil that provides a 1.5 T magnetic field. The detector is described in detail elsewhere [20]. Two inner detector configurations were used. A 2.0 cm radius beam pipe and a 3-layer SVD was used for the first sample of 156 fb^{-1} , while a 1.5 cm radius beam pipe, a 4-layer SVD and a small-cell inner CDC were used to record the remaining 824 fb^{-1} [21].

We reconstruct the Ξ_c^+ via the $\Xi_c^+ \rightarrow \Xi^-\pi^+\pi^+$, $\Xi^- \rightarrow \Lambda\pi^-$, $\Lambda \rightarrow p\pi^-$ decay channel. Final-state charged

particles, p and π^+ , are identified using the information from the tracking (SVD, CDC) and charged-hadron identification (CDC, ACC, TOF) systems combined into likelihood ratios $\mathcal{L}(i:j) = \mathcal{L}_i/(\mathcal{L}_i + \mathcal{L}_j)$, where $i, j \in \{p, K, \pi\}$. The π^\pm particles are selected by requiring $\mathcal{L}(\pi:K) > 0.6$; this has about 90% efficiency. The criteria $\mathcal{L}(p:\pi) > 0.6$ and $\mathcal{L}(p:K) > 0.6$ are required for proton candidates from the Λ . The Λ particles are reconstructed from $p\pi^-$ pairs with about 98% efficiency. The three-momentum of the Λ is combined with that of a π^- track to reconstruct the helix trajectory of the Ξ^- candidate; this helix is extrapolated back toward the interaction point. A vertex fit is applied to the $\Xi^- \rightarrow \Lambda\pi^-$ decay and the χ^2 is required to be less than 50. We retain Ξ^- candidates whose mass is within $\pm 3.0 \text{ MeV}/c^2 (\pm 3\sigma)$ of the nominal Ξ^- mass. Then, we combine the Ξ^- with two π^+ candidates, where the pion with the lower (higher) momentum is labeled π_L^+ (π_H^+). The closest distance between the π^+ track and the nominal e^+e^- interaction point must satisfy $|dz| < 1.3 \text{ cm}$ along the beam direction, and $|dr| < 0.16(0.13) \text{ cm}$ in the transverse plane for π_L^+ (π_H^+) for both π_L^+ and π_H^+ . A vertex fit is applied to the $\Xi_c^+ \rightarrow \Xi^-\pi^+\pi^+$ decay. The χ^2 is required to be less than 50. To purify the Ξ_c^+ samples, the scaled momentum $x_p = p_{\text{c.m.}}/\sqrt{\frac{1}{4}s - m(\Xi_c^+)^2}$ is required to exceed 0.5, where $p_{\text{c.m.}}$ is the momentum of Ξ_c^+ in the e^+e^- center-of-mass system, s is the squared total center-of-mass energy, and $m(\Xi_c^+)$ is the Ξ_c^+ nominal mass. We retain Ξ_c^+ candidates that satisfy $|M(\Xi^-\pi^+\pi^+) - m(\Xi_c^+)| < 12.7 \text{ MeV}/c^2$. The region $30.0 \text{ MeV}/c^2 < |M(\Xi^-\pi^+\pi^+) - m(\Xi_c^+)| < 55.4 \text{ MeV}/c^2$ defines the sideband for estimation of the combinatorial background.

The $M(\Xi^-\pi_L^+)$ and $M(\Xi^-\pi_H^+)$ distributions of the final sample are shown in Fig. 1(a). Peaks corresponding to $\Xi(1530)^0$, $\Xi(1620)^0$, and $\Xi(1690)^0$ are observed in the $M(\Xi^-\pi_L^+)$ distribution. A reflection due to $\Xi(1530)^0$ decays is seen around $2.2 \text{ GeV}/c^2$ in $M(\Xi^-\pi_H^+)$. The hatched histograms are the distributions of the Ξ_c^+ sideband events, where only the $\Xi(1530)^0$ is observed. The Dalitz plot of

FIG. 1. (a) The $\Xi^-\pi_L^+$ (solid) and $\Xi^-\pi_H^+$ (dashed) invariant mass distributions in the Ξ_c^+ signal region, as well as the corresponding distributions (hatched) in the Ξ_c^+ sideband region. (b) The Dalitz distribution for $\Xi_c^+ \rightarrow \Xi^-\pi_L^+\pi_H^+$.

$M^2(\Xi^-\pi_L^+)$ vs $M^2(\Xi^-\pi_H^+)$ is shown in Fig. 1(b). The cluster of events due to the $\Xi(1530)^0$ is seen. The region $4.3\text{--}5.3 (\text{GeV}/c^2)^2$ in $M^2(\Xi^-\pi_H^+)$ contains the $\Xi(1620)^0$ and $\Xi(1690)^0$ signals. There are currently no known particles with a mass in the range of $2.1\text{--}2.3 \text{ GeV}/c^2$ that would decay into $\Xi\pi$. Such massive particles would decay predominantly into a three-particle final state such as $\Xi\pi\pi$. The peaks around 1.60 and $1.69 \text{ GeV}/c^2$ in $M(\Xi^-\pi_L^+)$ are interpreted as the $\Xi(1620)^0$ and $\Xi(1690)^0$ resonances. We see an unknown structure in the range $1.8\text{--}2.1 \text{ GeV}/c^2$ in $M(\Xi^-\pi^+)$. These events are expected to be due to resonances such as $\Xi(1820)^0$, $\Xi(1950)^0$, and $\Xi(2030)^0$.

The correction of the event-reconstruction efficiency is applied to the mass spectrum. To calculate this efficiency, we generate MC events for the nonresonant three-body decay $\Xi_c^+ \rightarrow \Xi^-\pi^+\pi^+$ with a uniform distribution in phase space. The efficiency is the number of events surviving the selections divided by the total number of generated events, and is measured as a function of $M(\Xi^-\pi_L^+)$; the resulting efficiency is from 0.082 to 0.097 and shows a nearly flat distribution in $M(\Xi^-\pi_L^+)$. The mass distribution is divided by this efficiency and is normalized by the total number of events.

We perform a binned maximum-likelihood fit to the efficiency-corrected $M(\Xi^-\pi_L^+)$ distribution. The fit is applied for the data samples in the signal region and the sideband region simultaneously. The fitting range is restricted to $(1.46, 1.76) \text{ GeV}/c^2$ to avoid inclusion of the unknown structure between 1.8 and $2.1 \text{ GeV}/c^2$. The fitting function for the mass spectrum in the signal region includes resonances due to the $\Xi(1530)^0$, $\Xi(1620)^0$, and $\Xi(1690)^0$, a nonresonant contribution, and the combinatorial background. The fitting function for the mass spectrum in the sideband region includes the $\Xi(1530)^0$ signal and the combinatorial background. The shape of the fitting function for the combinatorial backgrounds is common for the mass spectra in the signal region and the sideband region, and is made by a function with a threshold: $u^a \exp(ub) + cu$, where $u = 1 - [(2 - M)/(2 - d)]^2$ and $M = M(\Xi^-\pi_L^+)$; a , b , c , and d are free parameters. We assume an S -wave nonresonant contribution, and generate the distribution from the MC simulation of $\Xi_c^+ \rightarrow \Xi^-\pi^+\pi^+$ decays with a uniform distribution in phase space. The $\Xi(1620)^0$ signal is modeled with the S -wave relativistic Breit-Wigner function. The $\Xi(1530)^0$ and $\Xi(1690)^0$ signals are modeled with P - and S -wave relativistic Breit-Wigner functions convolved with a fixed Gaussian resolution function of width 1.38 and $2.04 \text{ MeV}/c^2$, respectively, as determined from the MC simulation. The width and mass of $\Xi(1530)^0$ and $\Xi(1620)^0$ particles are floated in the fit. The mass and width of the $\Xi(1690)^0$ are fixed in the fit to the values $(1686 \text{ MeV}/c^2$ and 10 MeV , respectively) measured by the WA89 Collaboration [22]. The interference between the $\Xi(1620)^0$ and the S -wave nonresonant

FIG. 2. (a) The $\Xi^- \pi_L^+$ invariant mass spectrum in the signal region (points with error bars), together with the fit result (solid blue curve) including the following components: $\Xi(1530)^0$ signal (dashed red curve), $\Xi(1690)^0$ signal (dot-dashed pink curve), $\Xi(1620)^0$ signal and nonresonant contribution (dot-dashed black curve), the combinatorial backgrounds (dotted black curve). The bottom plots show the normalized residuals (pulls) of the fits. (b) The $\Xi^- \pi_L^+$ invariant mass spectrum in the sideband region (points with error bars), together with the fit result (solid blue curve) including the following components: $\Xi(1530)^0$ signal (dashed red curve), and the combinatorial backgrounds (dotted black curve).

process is taken into account, and these are coherently added. We check the interference of the $\Xi(1690)^0$ to the S -wave nonresonant process and the $\Xi(1620)^0$ by applying the fit with the interference term, and it is negligible. Figure 2(a) and 2(b) show the $\Xi^- \pi_L^+$ mass spectrum in the signal region and the sideband region with the fitting result, respectively. The χ^2/ndf (where ndf is the number of degrees of freedom) is 66/86. For the $\Xi(1620)^0$ and the $\Xi(1690)^0$ resonance, fits are repeated by fixing each yield to zero; the resulting difference in log-likelihood with respect to the nominal fit and the change of the number of degrees of freedom are used to obtain the statistical significance. Taking the systematic uncertainties mentioned later into account, the signal significance of the $\Xi(1620)^0$ is obtained to be 25σ . The statistical significance of the $\Xi(1690)^0$ is 4.5σ . When the P -wave-only relativistic Breit-Wigner function with fixed mass and width is used as the fitting function, the significance is 4.0σ . When the S -wave-only relativistic Breit-Wigner function with the floated mass and width is used, the significance is 4.6σ . We take the minimum value of 4.0σ as the significance including the systematic uncertainty. The measured mass and width of $\Xi(1530)^0$ are $1533.4 \pm 0.4 \text{ MeV}/c^2$ and $11.2 \pm 1.5 \text{ MeV}$, respectively. The measured mass and width of $\Xi(1620)^0$ are $1610.4 \pm 6.0 \text{ MeV}/c^2$ and $60.0 \pm 4.8 \text{ MeV}$, respectively. The mass resolution (σ) at $1600 \text{ MeV}/c^2$ is $1.6 \text{ MeV}/c^2$ as determined from the

TABLE I. Systematic uncertainties for the mass and the width of $\Xi(1620)^0$.

Source	Mass (MeV/c^2)	Width (MeV)
Mass scale	-1.5	-2.7
Mass shape of $\Xi(1620)$	+4.5	+1.8
Mass shape of $\Xi(1690)$	+2.3	+1.7
Nonresonant contribution	-2.3	+0.3/ - 3.8
Interference with $\Xi(1690)$	+1.3	-5.2
Bin size	± 3.1	± 1.3

MC simulation. The width of the $\Xi(1620)^0$ is 59.9 MeV after incorporating this mass resolution.

We itemize the systematic uncertainties on the mass and width of the $\Xi(1620)^0$ resonance in Table I. The mass scale and width is checked by comparing the reconstructed mass of the $\Xi(1530)^0$ in the $\Xi^- \pi^+$ channel with the nominal mass. The differences of the mass and width are $-1.5 \text{ MeV}/c^2$ and -2.7 MeV , respectively. We then generate and simulate $\Xi_c^+ \rightarrow \Xi^* \pi^+$, $\Xi^* \rightarrow \Xi^- \pi^+$ events and analyze them by the same program as for the real data; the mass scale is checked by comparing the reconstructed mass of Ξ^* with the generated mass. Here, the difference of the mass is $-0.2 \text{ MeV}/c^2$ and the difference of the width is less than the statistical error. The systematic uncertainties due to the mass shapes of the $\Xi(1620)^0$ and $\Xi(1690)^0$ are obtained by the fitting their masses and widths after switching each to the P -wave relativistic Breit-Wigner function instead of the nominally used S -wave form. Deviation from pure phase space for the nonresonant contribution is possible, and we estimate this systematic uncertainty by multiplying the nominal phase-space distribution with a third-order polynomial passing the kinematical lower bound of $M(\Xi^- \pi^+)$ and refitting. The systematic uncertainty from possible interference between the $\Xi(1690)^0$ and the nonresonant component is estimated by comparing the fit results with and without interference applied. The nominal bin width of the mass spectrum is $3.0 \text{ MeV}/c^2$. We determine its systematic uncertainty by changing the bin size from 2.5 to $3.5 \text{ MeV}/c^2$ and refitting.

All of the above sources are uncorrelated, so the total systematic uncertainties are calculated by summing them in quadrature.

We refit the data using a function that excludes the interference between $\Xi(1620)^0$ and the S -wave nonresonant process. The χ^2/ndf is 80/87, which is worse than the nominal fit result (66/86). The refitted mass and width of the $\Xi(1620)^0$ are $1601.2 \pm 1.5 \text{ MeV}/c^2$ and $63.6 \pm 8.7 \text{ MeV}$, respectively.

For the first time, the $\Xi(1620)^0$ particle is observed in its decay to $\Xi^- \pi^+$ via $\Xi_c^+ \rightarrow \Xi^- \pi^+ \pi^+$ decays. The number of $\Xi(1620)^0$ events is 2 orders of magnitude larger than that in

previous experiments. The measured mass and width of the $\Xi(1620)^0$ are consistent with the results of previous measurements within the large uncertainties of the latter and are much more precise. The width of the $\Xi(1620)^0$ is somewhat larger than that of the other Ξ^* particles [1].

The constituent quark models have predicted the first excited states of Ξ around $1800 \text{ MeV}/c^2$ [3]; therefore, it is difficult to explain the structure of the $\Xi(1620)^0$ and $\Xi(1690)^0$ in this context. Instead, it implies that these states are candidates of a new class of exotic hadrons. We observe in the low-mass region two states with a mass difference of about $80 \text{ MeV}/c^2$: the $\Xi(1620)^0$ is strongly coupled to $\Xi\pi$ and the $\Xi(1690)^0$ to ΣK . The situation is similar to the two poles of the $\Lambda(1405)$ [4] and suggests the possibility of two poles in the $S = -2$ sector. Studying these states may explain the riddle about the $\Lambda(1405)$; consequently, the interplay between the $S = -1$ and $S = -2$ states can help resolve this longstanding problem of hadron physics.

The $\Xi(1620)^0$ and $\Xi(1690)^0$ particles are found in the decay of Ξ_c^+ while their signals are not seen in the sideband events of Fig. 1(a). These results offer a clue for understanding the quark structure of these exotic states. The result indicates that the hadronic decays of charmed baryons via charm-to-strange quark transitions are potentially a promising system for further studies of strange baryons [16].

We thank the KEKB group for the excellent operation of the accelerator; the KEK cryogenics group for the efficient operation of the solenoid; and the KEK computer group, and the Pacific Northwest National Laboratory (PNNL) Environmental Molecular Sciences Laboratory (EMSL) computing group for strong computing support; and the National Institute of Informatics, and Science Information NETwork 5 (SINET5) for valuable network support. We acknowledge support from the Ministry of Education, Culture, Sports, Science, and Technology (MEXT) of Japan, the Japan Society for the Promotion of Science (JSPS), and the Tau-Lepton Physics Research Center of Nagoya University; the Australian Research Council including Grants No. DP180102629, No. DP170102389, No. DP170102204, No. DP150103061, and No. FT130100303; Austrian Science Fund under Grant No. P 26794-N20; the National Natural Science Foundation of China under Contracts No. 11435013, No. 11475187, No. 11521505, No. 11575017, No. 11675166, No. 11705209; Key Research Program of Frontier Sciences, Chinese Academy of Sciences (CAS), Grant No. QYZDJ-SSW-SLH011; the CAS Center for Excellence in Particle Physics (CCEPP); the Shanghai Pujiang Program under Grant No. 18PJ1401000; the Ministry of Education, Youth and Sports of the Czech Republic under Contract No. LTT17020; the Carl Zeiss Foundation, the Deutsche
