Exposure, Dose-Equivalent and Absorbed-Dose Buildup Factors of Gamma Rays for Plane Normal and Isotropic Incidences on Water, Concrete, Iron and Lead

Shun-ichi TANAKA and Kiyoshi TAKEUCHI*

Department of Reactor Engineering, Tokai Research
Establishment, JAERI

(Received January 23, 1984)

Exposure, dose-equivalent and absorbed-dose buildup factors are calculated using a discrete-ordinates direct integration code, PALLAS-PL,SP-Br, for water, concrete, iron and lead, typifying materials of low, medium, high atomic number for gamma-ray sources at plane normal and isotropic incidences. These data include the effects of secondary photon sources arising from Compton scattering, Bremsstrahlung and annihilation. Inclusion of Bremsstrahlung source has great influence on these buildup factors for high energy photons in materials of high atomic number.

The calculated buildup factors are tabulated for incident energies of 0.1 to 15 MeV (0.4 to 15 MeV only for lead) and penetration depths up to 40 mean-free-paths in each material.

Keyword : Exposure, Dose-equivalent, Absorbed-dose Buildup Factors, PALLAS-PL Code, SP-Br, Water, Concrete, Iron, Lead, Plane Normal, Isotropic Incidences, Bremsstrahlung, Annihilation, Gamma-ray

水，コンクリート，鉄，鉛に平板垂直入射
および平板等方入射の場合のガンマ線照射
再生係数，線量当量再生係数，吸収線量再
生係数

日本原子力研究所東海研究所原子炉工学部
田中俊一・竹内清*

(1984年1月23日受理)

平板垂直入射および等方入射ガンマ線について，小，中および大の原子番号をもつ典型的な物質である水，コンクリート，鉄，鉛に対して，ディスクリート・オーディネイト直接積分コードPALLAS-PL，SP-Brを用いて，照射再生係数，線量当量再生係数および吸収線量再生係数を計算した。これらのデータはコンプトン散乱，制動放射および消滅ガンマ線に起因する二次光子線源を考慮して求められている。制動放射線は大きな原子番号の物質におけるエネルギーの高い光子の場合にこれらの再生係数に大きな影響を及ぼす。

計算された再生係数は各物質毎に深さ4.0平均自由行程までについて，入射エネルギーが0.1 MeVから1.5 MeV（ただし，鉛のみについては0.4 MeVから1.5 MeV）までの各エネルギーに対して表の形にまとめられている。

1. INTRODUCTION

Buildup factors are always effective for practical calculations in gamma-ray shield design. The data calculated using a moments-method by Goldstein and Wilkins¹ have been extensively utilized throughout the world in gamma-ray shield calculations. However, these data are not only old (1954) but also limited up to 15 mean free path in depth. In addition, only Compton scattering was taken into account as secondary photon sources for these data.

The contribution of Bremsstrahlung and annihilation photons to the buildup factors is exceedingly large at high energies in materials of high atomic number. In a previous paper², we presented an approach to transport calculation of photons including those arising from the Bremsstrahlung and annihilation, and provided some comparisons of calculations with experiments in energy spectra in iron and lead as well as in transmitted dose through lead to test the validity of a discrete ordinates PALLAS-PL,SP-Br code³ designed based on the presented approach.

The object of the present work is to provide exposure, dose-equivalent and absorbed-dose buildup factors for typical shielding materials such as water, concrete, iron and lead for general use in gamma-ray shield design calculations. Our systematic calculations using the PALLAS-PL,SP-Br code include the effects of secondary sources arising from Compton scattering, Bremsstrahlung and annihilation. Plane normal and isotropic incidences are taken into account as gamma-ray sources with the incident energies of 0.1~15.0 MeV except for lead, in which the incident energies are limited to the range of 0.4~15.0 MeV because of neglection of fluorescence contribution. The effect of fluorescence on the dose buildup factor has been studied by Subbaiah, et al.⁴ to be spectacular for source energies close to the K edge.

2. CALCULATED DOSE BUILDUP FACTORS

Calculated three types of dose buildup factors are tabulated in tables 4~27. We define the types of dose buildup factor in the following: If the flux in a medium M is given as $\Phi(x, E)$, then

(1) dose equivalent rate, $D(x)$, is defined as

$$D(x) = \int_0^{E_{\max}} \Phi(x, E) \cdot K(E) dE,$$

where $K(E)$ is the flux to dose equivalent rate conversion factor ($\text{mrem} \cdot \text{hr}^{-1} / \text{n} \cdot \text{cm}^2 \cdot \text{sec}$),

(2) exposure dose rate, $D_e(x)$, is defined as

$$D_e(x) = \int_0^{E_{\max}} \Phi(x, E) \cdot K_e(E) dE,$$

where $K_e(E)$ is the flux to exposure dose rate conversion factor ($\text{mr} \cdot \text{hr}^{-1} / \text{n} \cdot \text{cm}^2 \cdot \text{sec}$),

and

(3) absorbed dose rate, $D_a(x)$, is defined as

$$D_a = \int_0^{E_{\max}} E \cdot \Phi(x, E) \frac{\mu_{en}(E)}{\rho} dE,$$

where $\mu_{en}(E)/\rho$ is the conversion coefficient from the energy flux to the energy absorbed dose rate when the Bremsstrahlung is taken into account in the calculations, while for exclusion of the Bremsstrahlung the energy transfer coefficient $\mu_k(E)/\rho$ is used instead of $\mu_{en}(E)/\rho$. These conversion factors are summarized in Table 1 for the present calculations. Table 2 gives the linear attenuation coefficients and the material

densities, which is convenient for shielding designers to calculate mfp of shield. These data are taken from Hubbell's compilation⁵. Table 3 gives the atomic composition of the ordinary concrete, which is taken from ANL-5800⁶.

The blanks in the item "with brems." mean that the buildup factors with taking the Bremsstrahlung into account are almost the same as those without it. The reason for lack of data for lead at the source energies of 0.1~0.3 MeV is due to that our calculations exclude the effect of the fluorescence photons. The fluorescence contribution to the buildup factors is considerably large at these low energies for heavy materials like lead: The data increase by ~13% at 0.3 MeV source, by ~80% at 0.2 MeV source and by a factor of 16 at 0.1 MeV source at 8-mfp depth⁴.
